ON AN IMPROVED RATIO TYPE ESTIMATOR OF
FINITE POPULATION MEAN IN SAMPLE SURVEYS
A K P C Swain
Former Professor of Statistics, Utkal University, Bhubaneswar-751004, India

ABSTRACT
In this paper an alternative ratio type exponential estimator is suggested and is compared with Bahl and Tuteja’s ratio type exponential estimator and classical ratio estimator as regards bias and mean square error with large sample approximations both theoretically and with numerical illustration.

KEYWORDS: Simple random sampling, ratio type estimators, Bias, Mean square error.

MSC: 62D05

RESUMEN
En este trabajo se sugiere un estimador del tipo razón-exponencial alternativo y se compara con el de Bahl y Tuteja el de razón clásico, considerando sesgo y error cuadrático medio, bajo aproximaciones basadas en muestras grandes y haciendo ilustraciones teóricas y numéricas.

1. INTRODUCTION:
The use of auxiliary information dates back to year 1934, when Neyman used it for stratification of the finite population. Cochran(1940) used auxiliary information in estimation procedure and proposed ratio method of estimation to provide more efficient estimator of the population mean or total compared to the simple mean per unit estimator under certain conditions when the auxiliary variable has positive correlation with the study variable in question.

Let \( U = (U_1, U_2, \ldots, U_N) \) be the finite population of size \( N \). To each unit \( U_i (i=1, 2\ldots, N) \) in the population paired values \( (y_i, x_i) \) corresponding to study variable \( y \) and an auxiliary variable \( x \), correlated with \( y \) are attached.

Now, define the population means of the study variable \( y \) and auxiliary variable \( x \) as
\[
\bar{Y} = \frac{1}{N} \sum_{i=1}^{N} y_i, \quad \bar{X} = \frac{1}{N} \sum_{i=1}^{N} x_i
\]
Thus, the population ratio is defined as
\[
R = \frac{\bar{Y}}{\bar{X}}
\]

Further, define the finite population variances of \( y \) and \( x \) and their covariance as
\[
S_y^2 = \frac{1}{N-1} \sum_{i=1}^{N} (y_i - \bar{Y})^2, \quad \text{and} \quad S_x^2 = \frac{1}{N-1} \sum_{i=1}^{N} (x_i - \bar{X})^2, \quad \text{and} \quad S_{yx} = \frac{1}{N-1} \sum_{i=1}^{N} (y_i - \bar{Y})(x_i - \bar{X}),
\]

Thus, the squared coefficients of variation of \( y \) and \( x \) and their coefficient of covariation are respectively defined by \( C_{20}, C_{02} \) and \( C_{11} \), where
\[
C_{rs} = \frac{1}{N} \sum_{i=1}^{N} (y_i - \bar{Y})^r (x_i - \bar{X})^s, \quad r,s = 0,1,2,\ldots
\]

Define \( \rho \) as the correlation coefficient between \( Y \) and \( X \) in the population.

A simple random sample ‘s’ of size \( n \) is selected from \( U \) without replacement and the values \( (y_i, x_i), i=1, 2 \ldots n \) are observed on the sampled units. Assume that \( Y \) and \( X \) are positively correlated. The simple mean \( \bar{Y} \) is an unbiased estimator of the population mean \( \bar{Y} \) and variance of \( \bar{Y} \) is given by
\[
\text{Var}(\bar{Y}) = \theta \bar{Y}^2 C_{20}
\]

The classical ratio estimator of the population mean \( \bar{Y} \) using auxiliary information on \( X \) is given by
\[ \bar{y}_R = \frac{\bar{y}}{\bar{x}} \bar{X}, \]  
(1.1)

where \( \bar{y} \) and \( \bar{x} \) are sample means of \( y \) and \( x \) respectively, defined by \( \bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i \) and \( \bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i \).

The ratio estimator \( \bar{y}_R \) envisages advance knowledge of \( \bar{X} \). The bias (\( \hat{B} \)) and mean square error (\( MSE \)) of \( \bar{y}_R \) to \( O(1/n) \) are given by (see Sukhatme and Sukhatme, 1970)

\[ B(\bar{y}_R) = \theta \bar{Y} (C_{02} - C_{11}) \]  
(1.2)

\[ MSE(\bar{y}_R) = \theta \bar{Y}^2 (C_{20} + C_{02} - 2C_{11}) \]  
(1.3)

where

\[ \theta = \frac{N - n}{(N-1)n} , \quad C_{rs} = \frac{1}{N} \sum_{i=1}^{N} (y_i - \bar{Y})^r (x_i - \bar{X})^s , \quad r, s = 0, 1, 2 \]

The ratio estimator \( \bar{y}_R \) is a biased estimator and the bias decreases with increase in sample size.

In large samples \( \bar{y}_R \) is more efficient than the simple mean per unit estimator \( \bar{y} \) if

\[ k = \rho \sqrt{\frac{C_{20}}{C_{02}}} > \frac{1}{2} \]

or if \( \rho > \frac{1}{2} \) when \( C_{20} = C_{02} \).

Bahl and Tuteja (1991) have suggested a ratio type exponential estimator given by

\[ \bar{y}_{BTR} = \bar{y} \exp\left( \frac{\bar{X} - \bar{x}}{\bar{X} + \bar{x}} \right) \]  
(1.4)

To \( O(1/n) \), the bias and mean square error of \( \bar{y}_{BTR} \) are given by

\[ B(\bar{y}_{BTR}) = \theta \bar{Y} \left( \frac{3}{8} C_{02} - \frac{1}{2} C_{11} \right) \]  
(1.5)

\[ MSE(\bar{y}_{BTR}) = \theta \bar{Y}^2 \left( C_{20} + \frac{1}{4} C_{02} - C_{11} \right) \]  
(1.6)

\( \bar{y}_{BTR} \) is more efficient than \( \bar{y}_R \) and \( \bar{y} \) if \( \frac{1}{4} < k < \frac{3}{4} \). (Bahl and Tuteja, 1991):

Upadhyaya, Singh, Chatterjee and Yadav (2011) have shown that for \( O(1/n^2) \), Bahl and Tuteja’s (1991) ratio type exponential estimator is more efficient than the classical ratio estimator \( \bar{y}_R \) when \( y \) and \( x \) follow bivariate normal distribution, coefficients of variation of \( y \) and \( x \) are equal and

\[ 0 < \rho < \frac{3}{4} \]

In the following we suggest a ratio type estimator with square root transformation and compare it with the Bahl-Tuteja’s (1991) ratio type exponential estimator and classical ratio estimator both theoretically and with the help of some natural and artificial populations.

2. A RATIO TYPE ESTIMATOR USING SQUARE ROOT TRANSFORMATION

Define the ratio type estimator using square root transformation as
\( \overline{y}_{SQR} = \overline{y} \left( \frac{\overline{X}}{X} \right)^{1/2} \)

(2.1)

2.1. Bias and Mean square error of \( \overline{y}_{SQR} \)

Write \( \overline{y} = \overline{Y}(1 + e_0) \) and \( \overline{X} = \overline{X}(1 + e_1) \) with \( E(e_0) = E(e_1) = 0 \). \( V(e_0) = \theta C_{02} \). \( V(e_1) = \theta C_{02} \) and \( \text{Cov}(e_0, e_1) = \theta C_{11} \).

Expanding \( \overline{y}_{SQR} \) in power series under the assumption that \( |e_1| < 1 \) for all possible samples and retaining terms up to fourth degree in \( e_0 \) and \( e_1 \), we have

\[
\overline{y}_{SQR} = \overline{Y} + \overline{Y}(e_0 - \frac{1}{2} e_1 + \frac{3}{8} e_1^2 - \frac{15}{48} e_1^3 + \frac{105}{384} e_1^4 - \frac{1}{2} e_0 e_1 + \frac{3}{8} e_0^2 e_1 - \frac{15}{48} e_0 e_1^3) \]

(2.2)

\[
(\overline{y}_{SQR} - \overline{Y})^2 = \overline{Y}^2 \left[ (e_0^2 + \frac{1}{4} e_1^2 - e_0 e_1) + e_0^2 e_1^2 + \frac{5}{4} e_0 e_1^2 - e_0 e_1^3 - \frac{33}{24} e_0^2 e_1^3 - \frac{3}{8} e_1^3 + \frac{87}{192} e_1^4 \right] \]

(2.3)

Thus,

\[
B(\overline{y}_{SQR}) = \overline{Y} \left[ E(e_0) - \frac{1}{2} E(e_1) + \frac{3}{8} E(e_1^2) - \frac{15}{48} E(e_1^3) + \frac{105}{384} E(e_1^4) \right] - \frac{1}{2} E(e_0 e_1) + \frac{3}{8} E(e_0^2 e_1) - \frac{15}{48} E(e_0 e_1^3) \]

(2.4)

\[
\text{MSE}(\overline{y}_{SQR}) = E(\overline{y}_{SQR} - \overline{Y})^2 = \overline{Y}^2 \left[ E(e_0^2) + \frac{1}{4} E(e_1^2) - E(e_0 e_1) \right] + \overline{Y}^2 \left[ \frac{5}{4} e_0 e_1^2 - E(e_0 e_1^2) - \frac{33}{24} E(e_0 e_1^3) - \frac{3}{8} E(e_1^3) + \frac{87}{192} E(e_1^4) \right] \]

(2.5)

Now,

\[
E(e_1^4) = \frac{N-n}{n^3} \left[ \frac{N^2 + N - 6nN + 6n^2}{(N-1)(N-2)(N-3)} C_{04} + \frac{3N(N-n-1)(n-1)}{(N-1)(N-2)(N-3)} C_{02} \right] \]

\[
E(e_0 e_1^3) = \frac{N-n}{n^3} \left[ \frac{N^2 + N - 6nN + 6n^2}{(N-1)(N-2)(N-3)} C_{13} + \frac{3N(N-n-1)(n-1)}{(N-1)(N-2)(N-3)} C_{11} C_{02} \right] \]

\[
E(e_0^2 e_1^2) = \frac{N-n}{n^3} \left[ \frac{N^2 + N - 6nN + 6n^2}{(N-1)(N-2)(N-3)} C_{22} + \frac{N(N-n-1)(n-1)}{(N-1)(N-2)(N-3)} (C_{20} C_{02} + 2 C_{11}^2) \right] \]

\[
E(e_1^3) = \frac{(N-n)(N-2n)}{(N-1)(N-2)n^2} C_{03} \]

\[
E(e_0^2 e_1) = \frac{(N-n)(N-2n)}{(N-1)(N-2)n^2} C_{12} \]

\[
E(e_0^4) = \frac{(N-n)(N-2n)}{(N-1)(N-2)n^2} C_{21} \]

where

\[
C_{rs} = \frac{1}{N} \sum_{i=1}^{N} (y_i - \overline{Y})^r (x_i - \overline{X})^s / \overline{Y}^r \overline{X}^s \quad (r, s = 1, 2, 3, 4). \]
Hence,
\[ B(\bar{Y}_{SQR}) = \bar{Y} \frac{N-n}{N-1} \left[ \frac{3}{8} C_{02} - \frac{1}{2} C_{11} \right] \]
\[ + \bar{Y} \frac{N-n}{N-1} \left[ \frac{A}{n} \left( C_{12} - \frac{15}{48} C_{03} \right) + \frac{B}{n^2} \left( C_{04} - \frac{15}{48} C_{13} \right) \right] \]
\[ + \frac{3D}{n^2} \left( \frac{105}{384} C_{02} - \frac{15}{48} C_{11} C_{02} \right) \]  \hspace{1cm} (2.6)
\[ \text{MSE}(\bar{Y}_{SQR}) = \bar{Y}^2 \frac{N-n}{N-1} \left[ \left( C_{20} + \frac{1}{4} C_{02} - C_{11} \right) + \frac{1}{n} A \left( C_{12} - C_{21} - \frac{3}{8} C_{03} \right) \right] \]
\[ + \bar{Y}^2 \frac{N-n}{N-1} \left[ \frac{1}{n^2} B \left( \frac{87}{192} C_{04} + C_{22} - \frac{33}{24} C_{13} \right) + \frac{1}{n} D \left( C_{20} C_{02} + 2C_{11}^2 - \frac{33}{8} C_{11} C_{02} + \frac{87}{64} C_{02}^2 \right) \right] \]
\[ \text{where} \quad A = \frac{N-2n}{N-2}, \quad B = \frac{N^2 + N - 6nN + 6n^2}{(N-2)(N-3)}, \quad D = \frac{N(N-n-1)(n-1)}{(N-2)(N-3)} \]

### 2.2. Bias and Mean Square Error of $\bar{Y}_{BTR}$

Expanding $\bar{Y}_{BTR}$ in power series with the same assumptions used in expanding $\bar{Y}_{SQR}$ and retaining terms up to and including degree four in $e_0$ and $e_1$, we have

\[ \bar{Y}_{BTR} - \bar{Y} = \bar{Y} \left( e_0 - e_1 + \frac{3}{8} e_1^2 - e_0 e_1 + \frac{73}{384} e_1^4 - \frac{13}{48} e_1 \right) \]

\[ (\bar{Y}_{BTR} - \bar{Y})^2 = \bar{Y}^2 \left( e_0^2 + \frac{1}{4} e_1^2 - e_0 e_1 + \frac{5}{4} e_0 e_1^2 - e_0^2 e_1 - \frac{3}{8} e_1^3 + \frac{79}{192} e_1^4 + e_0^2 e_1^2 - \frac{31}{24} e_0^2 e_1 \right) \]

\[ B(\bar{Y}_{BTR}) = \bar{Y} \frac{N-n}{N-1} \left[ \frac{3}{8} C_{02} - \frac{1}{2} C_{11} \right] \]
\[ + \bar{Y} \frac{N-n}{N-1} \left[ \frac{A}{n} \left( C_{12} - \frac{13}{48} C_{03} \right) + \frac{B}{n^2} \left( \frac{73}{384} C_{04} - \frac{13}{48} C_{13} \right) \right] \]
\[ + \frac{D}{n^2} \left( \frac{73}{128} C_{02}^2 - \frac{13}{16} C_{02} C_{11} \right) \]  \hspace{1cm} (2.8)
\[ \text{MSE}(\bar{Y}_{BTR}) = E((\bar{Y}_{BTR} - \bar{Y})^2) = \bar{Y}^2 E(e_0^2 + \frac{1}{4} e_1^2) \]
\[ + \bar{Y}^2 E(e_0 e_1^2 - e_0 e_1) + \bar{Y}^2 E(e_0^2 e_1 - \frac{3}{8} e_1^3 + \frac{79}{192} e_1^4 + e_0^2 e_1^2 - \frac{31}{24} e_0^2 e_1) = \bar{Y}^2 \frac{N-n}{N-1} \left[ \left( C_{20} + \frac{1}{4} C_{02} - C_{11} \right) + \frac{1}{n} A \left( C_{12} - C_{21} - \frac{3}{8} C_{03} \right) + \frac{5}{4} \right] \]
\[ + \frac{1}{n^2} \left[ \frac{79}{192} C_{04} + C_{22} - \frac{31}{24} C_{13} \right] + \frac{1}{n^2} D \left( C_{20} C_{02} + 2C_{11}^2 - \frac{31}{8} C_{11} C_{02} + \frac{79}{64} C_{02}^2 \right) \]  \hspace{1cm} (2.9)

### 2.3. Bias and Mean Square Error of $\bar{Y}_{R}$

(See Sukhatme, Sukhatme and Asok (1984))
We find (see Sukhatme, Sukhatme and Asok, 1984) to second order approximation

\[ B(\mathcal{R}_R) = \mathcal{Y}^2 N^{-1} \frac{n}{n} (C_{o2} - C_{11}) + \mathcal{Y}^2 N^{-1} \frac{n}{n} \left[ \frac{1}{n} (C_{12} - C_{03}) + \frac{1}{n^2} (C_{04} - C_{13}) + 3D \frac{1}{n^2} (C_{02} - C_{11}) \right] \]  

(2.10)

\[ MSE(\mathcal{R}_R) = \mathcal{Y}^2 N^{-1} \frac{n}{n} \left[ (C_{20} + C_{02} - 2C_{11}) + \frac{2}{n} A(2C_{12} - C_{21} - C_{03}) \right] + \mathcal{Y}^2 N^{-1} \frac{n}{n} \left[ \frac{3}{n^2} B(C_{04} + C_{22} - 2C_{13}) + \frac{3}{n^2} D(C_{20}C_{02} + 2C_{11} - 6C_{10} + 3C_{02}^2) \right] \]  

(2.11)

Under the assumption of bivariate normality of \((y, x)\) and equality of coefficients variation of \(y\) and \(x\), i.e. \(C_{20} = C_{02}\), it may be shown that

\[ MSE(\mathcal{R}_R) = \mathcal{Y}^2 \frac{C_{02}}{n} \left[ 2(1 - \rho) + \frac{C_{02}}{n} (12 - 18\rho + 6\rho^2) \right] \]  

(2.12)

\[ MSE(\mathcal{R}_{BTR}) = \mathcal{Y}^2 \frac{C_{02}}{n} \left[ \frac{5}{4} - \rho \right] + \frac{C_{02}}{n} \left[ \frac{143}{64} - \frac{31}{8} \rho + 2\rho^2 \right] \]  

(2.13)

\[ MSE(\mathcal{R}_{SQR}) = \mathcal{Y}^2 \frac{C_{02}}{n} \left[ \frac{5}{4} - \rho \right] + \frac{C_{02}}{n} \left[ \frac{151}{64} - \frac{33}{8} \rho + 2\rho^2 \right] \]  

(2.14)

3. COMPARISON OF EFFICIENCY

(i) Considering terms up to \(O(1/n)\),

\[ MSE(\mathcal{R}_R) = \mathcal{Y}^2 \theta (C_{20} + C_{02} - 2C_{11}) \]

\[ MSE(\mathcal{R}_{SQR}) = MSE(\mathcal{R}_{BTR}) = \mathcal{Y}^2 \theta (C_{20} + \frac{1}{4} C_{02} - C_{11}) \]

\[ B = B(\mathcal{R}_R) = \mathcal{Y} \theta (C_{02} - C_{11}) \]

\[ B_1 = B(\mathcal{R}_{BTR}) = \mathcal{Y} \theta (\frac{3}{8} C_{02} - \frac{1}{2} C_{11}) \]

Now,

\[ MSE(\mathcal{R}_R) - MSE(\mathcal{R}_{SQR}) = MSE(\mathcal{R}_R) - MSE(\mathcal{R}_{BTR}) = \mathcal{Y}^2 \theta (\frac{3}{4} C_{02} - C_{11}) \]

Thus, to \(O(1/n)\), \(\mathcal{R}_{BTR}\) and \(\mathcal{R}_{SQR}\) are equally efficient. They are more efficient than \(\mathcal{R}_R\)

if \(\frac{C_{11}}{C_{02}} < \frac{3}{4}\)

or \(k < \frac{3}{4}\).

and more efficient than \(\mathcal{Y}\) if \(k > \frac{1}{4}\).

Hence, \(\mathcal{R}_{SQR}\) and \(\mathcal{R}_{BTR}\) are more efficient than both \(\mathcal{R}_R\) and \(\mathcal{Y}\) if \(\frac{1}{4} < k < \frac{3}{4}\).

Further, to \(O(1/n)\) the biases of \(\mathcal{R}_{SQR}\) and \(\mathcal{R}_{BTR}\) are equal and further they are less biased than \(\mathcal{R}_R\) if \(k\) is either greater than \(5/4\) or less than \(11/12\).

(ii) To \(O(1/n^2)\), for large \(N\),
\[ MSE(\bar{y}_{SQR}) - MSE(\bar{y}_{BTR}) = \begin{bmatrix} \frac{87}{192} - \frac{79}{192} \end{bmatrix} E(e_1^2) - \begin{bmatrix} \frac{33}{24} - \frac{31}{24} \end{bmatrix} E(e_0^2) \] 

Hence, \( \bar{y}_{SQR} \) will be more efficient than \( \bar{y}_{BTR} \) to \( O(1/n^2) \)

\[
\begin{align*}
&\text{if } \frac{1}{2} c_{02} - c_1 c_{02} < 0 \\
&\text{or } \frac{c_1}{c_{02}} > \frac{1}{2} \\
&\text{or } \rho > \frac{1}{2} \text{ when } c_{20} = c_{02}
\end{align*}
\]

Under bivariate normality of \( y \) and \( x \) with the assumption that \( C_{20} = C_{02} \) and the correlation coefficient between \( y \) and \( x \) equal to \( \rho \) we have

\[ MSE(\bar{y}_{BTR}) - MSE(\bar{y}_R) = \frac{1}{n} \bar{y}^2 C_{02} \left[ (\rho - \frac{3}{4}) - \frac{C_{02}}{n} \left( \frac{625}{64} - \frac{113}{8} \rho + 4 \rho^2 \right) \right] \]

(see Upadhyaya et al, 2011 and correct the coefficient of \( \rho \) as -113/8 instead of -103/8)

\[ MSE(\bar{y}_{SQR}) - MSE(\bar{y}_R) = \frac{1}{n} \bar{y}^2 C_{02} \left[ (\rho - \frac{3}{4}) - \frac{C_{02}}{n} \left( \frac{617}{64} - \frac{111}{8} \rho + 4 \rho^2 \right) \right] \]

If \( \rho < \frac{3}{4} \), both \( MSE(\bar{y}_{BTR}) - MSE(\bar{y}_R) \) and \( MSE(\bar{y}_{SQR}) - MSE(\bar{y}_R) \) are negative. Hence, to \( O(1/n^2) \) the sufficient condition that both \( \bar{y}_{BTR} \) and \( \bar{y}_{SQR} \) are more efficient than \( \bar{y}_R \) is that

\[ 0 < \rho < \frac{3}{4} \]

Further, \( \bar{y}_{SQR} \) will be more efficient than \( \bar{y}_{BTR} \) if

\[ \rho > \frac{1}{2} \]

Hence, \( \bar{y}_{SQR} \) will be more efficient than \( \bar{y}_{BTR} \) and \( \bar{y}_R \) if

\[ \frac{1}{2} < \rho < \frac{3}{4} \]

To sum up under the assumptions of bivariate normality of \( y \) and \( x \) and the equality of coefficients of variation of \( y \) and \( x \), the preferred estimators for ranges of \( \rho \) are shown below in Table-1.

For the populations under consideration, the ratio type estimator with square root transformation is less biased than the classical ratio estimator. Further, for populations 5-12, the ratio type estimator with square root transformation is more efficient than the classical ratio estimator in the sense of having lesser mean square error.

Illustration 2
Consider a hypothetical population of size $N = 5$ as follows:

$y: 3 \ 5 \ 8 \ 4 \ 5$
$x: 5 \ 2 \ 6 \ 4 \ 3$

For a simple random sample (without replacement) of size $n = 2$, the exact biases and mean square errors of $\bar{y}_R$, $\bar{y}_{SQR}$ and $\bar{y}_{BTR}$ are given in Table 4.

Comments: As per Illustration 2
(i) The ratio type estimator with square root transformation and ratio type exponential estimator have nearly equal bias and efficiency and further they are less biased and more efficient than the classical ratio estimator.
(ii) The classical ratio estimator is less efficient than the simple mean per unit estimator $\bar{y}$, whereas the ratio type estimator with square root transformation and the ratio type exponential estimator are more efficient than $\bar{y}$.

5. CONCLUSIONS:

(i) To $O(1/n)$ $\bar{y}_{SQR}$ and $\bar{y}_{BTR}$ are equally efficient and more efficient than both $\bar{y}_R$ and $\bar{y}$ if $\frac{1}{4} < k < \frac{3}{4}$. To same order of approximation both $\bar{y}_{SQR}$ and $\bar{y}_{BTR}$ are less biased than $\bar{y}_R$ if $k$ is either greater than $\frac{5}{4}$ or less than $\frac{11}{12}$.

(ii) Under the assumption of bivariate normality of $(y, x)$ and equality of coefficients of variation of $y$ and $x$, to $O(1/n^2)$ $\bar{y}_{SQR}$ is more efficient than both $\bar{y}_R$ and $\bar{y}_{BTR}$ for $\frac{1}{2} < \rho < \frac{3}{4}$. However, for the values of $\rho$ in the range $\frac{3}{4} < \rho < 1$, $\bar{y}_R$ is to be preferred over $\bar{y}$, $\bar{y}_{SQR}$ and $\bar{y}_{BTR}$. 

\begin{tabular}{c|c|c|c|c}
8 & 0.04 & 0.33 & 0.001257 & 0.003364 & 267.62 \\
9 & 0.28 & 0.81 & 0.489244 & 0.865788 & 176.96 \\
10 & 0.26 & 0.77 & 0.000998 & 0.003546 & 355.31 \\
11 & 0.13 & 0.51 & 0.001324 & 0.002598 & 196.22 \\
12 & 0.02 & 0.37 & 0.634131 & 0.703661 & 107.57 \\
\end{tabular}
(iii) Numerical illustration with the help of twelve natural populations shows that there might arise situations when $\bar{y}_{SQR}$ is less biased and more efficient than $\bar{y}_R$ under large sample approximations. Also, for the artificial population under consideration $\bar{y}_{SQR}$ happens to be less biased and more efficient than $\bar{y}_R$. However, the difference between $\bar{y}_{SQR}$ and $\bar{y}_{BTR}$ as regards bias and mean square error is only marginal.
